

Threads API

Corrective evidence

auto-publishing | Meta app 1655751472297844 | 21 September 2026

Purpose and limits of this submission

The app remains restricted under Platform Term 7.e.i.2 after two responses. This local audit corrects overbroad statements in the previous response and documents further changes. **The particular enforcement cause has not been confirmed by Meta.** No live Threads post or Meta API probe was performed during this remediation.

Confirmed implementation gaps and corrections

Control	Earlier implementation	Current implementation
Human review	Disabling the approval setting allowed posts through.	Disabled approval now rejects publishing. Review chat ID is checked.
Quality checks	Disabling the guard bypassed checks.	Disabled checks now reject publishing; minimum body/language checks cannot be relaxed.
Affiliate ratio	The 30% rule did not apply below 10 prior posts.	Projected ratio is checked from the first affiliate candidate over 30 calendar dates.
Local ceilings	Configuration could raise thresholds.	At most 3 posts/day, 1 affiliate/day, 30% affiliate ratio. Settings may only tighten ceilings.
Replies and OAuth	Reply code remained callable; OAuth requested reply management.	Reply creation is disabled; future OAuth requests only basic and content-publish scopes.
Restricted app traffic	Publishing and token renewal schedules remained active.	Persistent hold blocks repository API paths; relevant schedules disabled and scheduler restarted.
Quota reliability	Corrupt state reset counters; concurrent runs could race.	Corrupt records block posts; local publishers serialize quota checks and writes.

These numeric and language thresholds are operator safeguards, not claimed Meta policy requirements. Earlier guard and approval settings were enabled; the audit does not establish that bypass switches were used. Changing future OAuth requests does not revoke previously granted scopes.

Verification and remaining request

Evidence snapshot: 2026-09-21T15:43:52.768664+09:00

Deployment and offline validation

A persistent local API hold is active. Missing or invalid hold state blocks access. Explicit API-access-deactivated errors also suspend further activity. Restoration requires an operator record of Meta reinstatement; the local command does not itself verify Meta status. Already in-flight requests and external tools are outside this control.

Scheduler restart loaded the disabled Threads schedules; registered daily slots decreased from 14 to 11. Other platform schedules were retained. The publishing, reply, profile, permalink, token and repository OAuth/URL-repair paths are covered by the hold.

Offline regression result: 16 passed. Command: `python -m pytest tests/test_threads_safety.py -q`. Coverage includes blocked networking during hold, gate-disable rejection, affiliate cold-start limits, corrupt quota state, concurrent publisher exclusion, cross-chat approval rejection, hold during approval and an approved publication using mocked HTTP responses.

Records and units

Record source	Observation	Interpretation
Previous CSV, Aug 25 - Sep 14	28 quality blocks; 14 no-approval events; 2 API rejections.	44 events, not 44 pipeline runs. Zero published posts did not mean zero API requests.
Retained ledger, Sep 14 evening - Sep 21	12 Threads-related pipeline runs; 12 quality-block messages and 6 approval-block messages.	Partial stderr tails only. These cannot prove complete traffic counts or account-wide activity.
Local publish queue	473 Threads records; last queued at 2026-08-17T19:01:12 (local KST).	Local queue history, not an independent account audit.

Request to Meta

Please conduct a manual review and identify the specific offending behavior, post IDs or request timestamps if available. Please clarify whether the unresolved issue concerns publishing behavior, app configuration/data handling or an associated account restriction, and specify the evidence or change still needed. Threads API activity will remain suspended while the restriction remains in place.

Supporting files and scope

Companion files: **appeal_text_v3.txt** and **local_audit.json**. The JSON contains an allowlist of configuration values, hold state, scheduler heartbeat, per-run signal counts and full SHA-256 hashes of changed controls and tests. It contains no access tokens, app secrets, cookies or post text.

Official technical reference: Meta Threads API collection
